IQRF platform

IQRF is a wireless license free platform for ISM bands (868 and 916 MHz). Compact transceiver module (TR) has built-in operating system (OS) and is fully user programmable in C language using powerful OS functions including RF (wireless) as well as SPI (4-wire serial) communication and complex IQMESH networking support. No link layer is provided, the entire functionality is fully up to user application.

Compatibility

TR module	current OS	modulation
TR-11A	v2.08	ASK
TR-21A v1.02 and v1.03		ASK
TR-31B	v2.10 for 3xB	ASK
TR-32B		ASK
TR-52B	v3.00	FSK
TR-53B		FSK

Communication is possible among TR modules with the same type of modulation only. OS v3.00 is compatible with 2.11 in STD mode only.

The modules are delivered with IQRF OS allowing realization of common networking device (Node) as well as network Coordinator (software selectable), both able to work additionally also as a router on background (see RF networking).

IQRF transceiver modules allow **upgrades** to current OS version. This service must be done by the manufacturer.

IQRF OS versions and history

Version	Main differences	Release	Status
v3.00 for 5xB	<ul style="list-style-type: none"> Up to 65 000 devices and up to 240 hops in IQMESH network New power management, 35 uA in XLP RX Discovery, real time transparent routing, low power routers Many other outstanding features 	Jan 2011	current for TR-52B and TR-53B
v2.11 for 5xB	<ul style="list-style-type: none"> RF power management supported (<code>setRFmode</code>, <code>checkRF</code>, ...) RF channels available selectable RF bit rate (provisionally for experimental purpose) 	Mar 2010	not for new designs for TR-52B and TR-53B
v2.10 for 5xB	In addition to that for 3xB: <ul style="list-style-type: none"> 868 MHz or 916 MHz band software selectable Enhanced battery check RF IC sleep mode supported 	Jan 2010	for TR-52B and TR-53B not for new designs
v2.10 for 3xB	<ul style="list-style-type: none"> concept of OS plug-ins RF power not limited during bonding green LED support, LED functions renamed User RAM limited to 0x1CF 	Dec 2009	current for TR-31B and TR-32B
v2.09	<ul style="list-style-type: none"> minor change in first falling to Sleep mode bonding robustness increased 	Jul 2009	not for new designs
v2.08	<ul style="list-style-type: none"> broadcast message support added implemented in TR-31B modules 	Oct 2008	current for TR-11A and TR-21A
		Nov 2008	
v2.07	<ul style="list-style-type: none"> bug in the <code>setLoggingOff()</code> function fixed Wake-up on pin change improved. To utilize it, the sequence <code>GIE = 0; RBIE = 1;</code> is required just before <code>iqrfSleep()</code>. 	Sep 2008	not for new designs
v2.06	<ul style="list-style-type: none"> minor change in routing 	Aug 2008	not for new designs
v2.05	<ul style="list-style-type: none"> higher RF noise immunity corrected transfer of MPRWx while not routing several minor bugs not affecting module functionality corrected 	Aug 2008	not for new designs
v2.04	<ul style="list-style-type: none"> <code>setNetworkFilteringOn()</code> switches just packet from active network (1 or 2), non-networking communication ignored Wake-up on pin change under user's control. Default disabled. To enable, set <code>RBIE = 1</code> before <code>iqrfSleep()</code>. Not compatible with previous versions (permanently enabled in Sleep up to v2.03). 	Jul 2008	internal release only
v2.03	<ul style="list-style-type: none"> BufferCOM size increased from 35B to 41B Number of nodes in one network increased from 128 to 239 Minor bug in routing fixed 	Jul 2008	not for new designs
v2.02	<ul style="list-style-type: none"> minor SPI bug fixed 	May 2008	not for new designs
v2.01	<ul style="list-style-type: none"> function <code>wipeBondNR()</code> added function <code>batteryValueOK()</code> added 	Mar 2008	not for new designs
v2.00	<ul style="list-style-type: none"> Much more effective, easier to use, higher performance Networking totally reworked. Extended capability. Complete IQMESH. SPI on background Encoded network communication Indirect RAM access Temperature measurement supported by OS Supports user application debugging directly by IQRF OS Many other improvements IDE – complete development environment with all SW tools integrated including effective debug tools 	Jan 2008	not for new designs
v1.14	previous generation	Jul 2007	not for new designs

OS Principles

The IQRF system is designed to allow using of RF wireless connection according to user's needs. Transceiver modules contain microcontrollers for controlling the transceiver operations and for executing of user defined functioning.

Patented IQRF transceiver module architecture has two software layers:

- Basic routines programmed in advance by the manufacturer. The set of such functions is called **operating system (OS)**.
- **Application layer** utilizes routines from the basic layer to customize the module for user specific operation.

In opposite to Solution stack, there is no need to compile protocol related routines, just the application is compiled. This approach reduces time and development costs significantly when creating connectivity applications.

OS offers software functions prepared in advance for all common user requirements. Thus, it is not necessary to create the whole user program by oneself (using microcontroller instructions and C commands only) but the user adds a user part of software to the OS only.

The user application so called „runs under the operating system“ which means that this is invoked from OS, uses OS functions and is (should be) under OS control.

OS functions need not run sequentially (next function invoked not until the preceding one is finished) but some operations can run so called “in background” (the function arranges execution of requested operations which runs independently and immediately returns the control back to superior program). In this way more processes can run “simultaneously”. Then the program structure is that besides of execution running sequentially “in foreground” several tasks in background can be running. IQRF OS allows to run even very complex operation including complete SPI communication protocol in background. This makes real-time programming really easy.

IQRF OS supports communications:

- **RF** (radio), including networks – in **peer-to-peer** and **IQMESH** topologies.
- Standard serial **SPI** (slave mode) interface for connection to peripherals or to PC (e.g. via CK-USB-04).

Other communications can be realized with a user program (I²C, UART, ...).

Complex standard communication interfaces (**USB**, **Ethernet**, **GSM**, ...) can be realized using IQRF gateways.

OS supports low power consumption of IQRF transceivers with the **Sleep** functions when operation of TR module or RF IC is reduced/stopped.

To increase the reliability the **watchdog** function is used. This is implemented in microcontroller hardware and controlled via user program.

Concept of OS plug-ins

IQRF operating system can be extended via optional plug-ins.

Plug-in is a SW module delivered (typically by the IQRF manufacturer) as a file with the `.IQRF` extension. It should be uploaded to the TR module by the IQRF IDE and an IQRF programmer (e.g. CK-USB-04). The procedure is similar to uploading a user program.

More plug-ins can be used at the same time.

To utilize a plug-in, corresponding header files (with the `.H` extension, also delivered with the plug-in) should be included to source program similarly to other system header files.

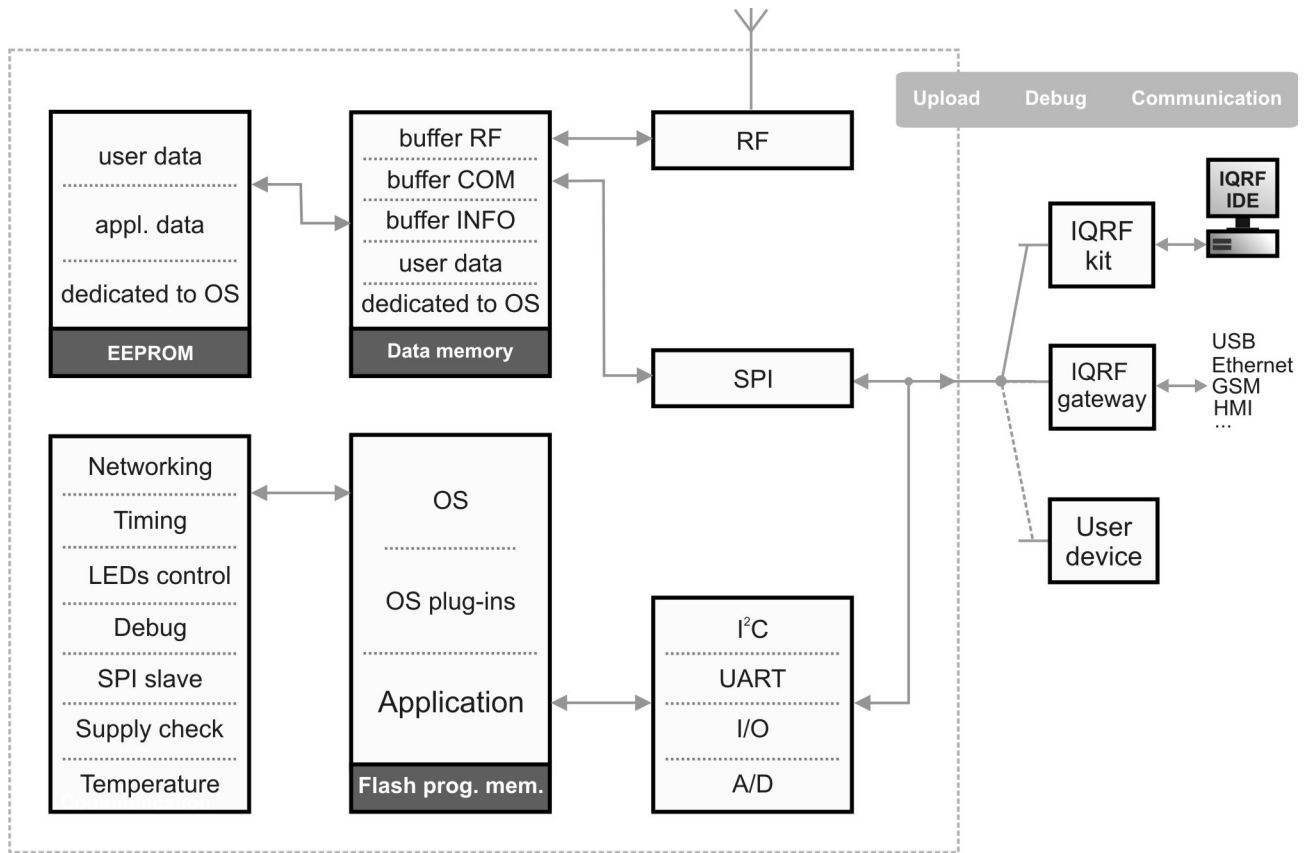

Example: `#include "plug-ins/PlugInXY.h"`

Then all plugged-in functions are available like standard system ones.

IQRF OS Architecture

Hardware of the transceiver module with a microcontroller including the IQRF OS results in architectural model:

Individual blocks:

- Memories:
 - program memory (Flash)
 - data memory (RAM)
 - data memory (EEPROM)
- Communication interface:
 - RF (wireless)
 - SPI (standard serial, 4-wire)
- Temperature sensor (TR-52B only)
- Power supply check
- Digital I/O (input/output).
- A/D converter
- Time base support: calibrated 10 ms interval (tick) generator in background and supporting functions
- 2 LEDs control in OS background
- IQMESH networking
- Debug: OS support for testing and debugging

Resources partially depend on transceiver module type.

RF circuitry

Main features:

- **Bands:** 868 MHz/916 MHz, SW selectable (default 868 MHz). Default 916 MHz on request.
- **Channels:** Frequency channels SW selectable in accordance with the CEPT ERC/REC 70-03 General License. See Appendix 2.
- **Bit rate:** SW selectable (1.2 kb/s, 19.2 kb/s, 57.6 kb/s and 86.2 kb/s). Default is 19.2 kb/s, other bit rates are provisionally intended for experimental purposes only. Routing is tested for 19.2 kb/s only.
- RF output power: up to 3.5 mW, SW selectable in 8 steps.
- Various **sleep** modes to reduce overall current consumption and optimize response times.
- RF RX and TX **power management** modes.

Microcontroller

IQRF OS for TR-52B, TR-53B and compatibles is implemented in the **PIC16F886** MCUs (8-bit microcontrollers by Microchip) – datasheet see [8].

PIC hardware resources and their utilization in TR modules with OS:

PIC HW resources		Utilization
Program memory	Flash	1024 instructions
Data memory	RAM	40 B – user data 172B – communication/system buffers
Data memory	EEPROM	Node: 160 B user data + 32B application data Coordinator: 0 B user data + 32B application data
I/O pins	TR-52B	6 × I/O
	TR-53B	7 × I/O
A/D converter (10b)		2 (TR-52B) or 3 (TR-53B) external analog inputs
Serial communication	SPI (slave)	Supported by OS in background
	I ² C	Realized by PIC HW module and user function – see Application examples [10]
	UART	Realized by PIC HW module and user function – see Application examples [10]
Interrupt		Not user available. It can be disabled just for a short period if necessary.
Stack (for subroutines, shared with interrupt)		Max. 2 levels of subroutine calling is allowed except of <code>RFTXpacket()</code> and <code>RFRXpacket()</code> (1 level allowed) and <code>bondNewnode()</code> , <code>bondRequest()</code> and <code>answerSystemPacket()</code> (must not be called in subroutines at all).
Power-on reset		Utilizes HW filter to eliminate improper power-up rising and spikes to some extent.
Brown-out reset		Enabled during operation and disabled in Sleep. Reset voltage level = 2.1V. Typical power-on reset and OS boot takes ~720 ms and depends on supply rise shape.
Power-up timer		Disabled
Watchdog		Default disabled in Configuration word and enabled by SW (can be disabled by SWDTEN bit). Time-out can be set from 1 ms to 268 s or disabled at all by SW, default ~ 4 s. WDT time-out varies with temperature, supply voltage and other conditions from part to part. See PIC datasheet [8].
Oscillator		Internal RC, 8 MHz (500ns instruction). Do not switch to another clock. IQMESH timing precision is not limited by precision of this oscillator when calibrated by the <code>calibrateTimer()</code> OS function.
Configuration words ("Fuses")		CONFIG1 = 0x2214, CONFIG2 = 0xFCFF

These resources can be under OS supervision and the user should access them in accordance with this manual and possible requirements resulting from hardware construction of the module and OS implementation.

Configuration changes and direct access to some resources by the user can be limited or not allowed at all. Serviceability of some resources depends on using of some other ones at the same time (some hardware communication modules, pins and memory areas are shared for more functions, ...).

Parts of memories are dedicated to PIC core, peripherals and operating system. Direct access (via the EEDATA register) to the EEPROM is not allowed at all, extra OS functions are intended for this. Flash memory is user accessible for uploading the program and OS plug-ins to the microcontroller using the IQRF development kits only. Indirect RAM access using the FSR register is not allowed due to security reasons. Instead of this IQRF OS provides complete support for indirect addressing using extra system functions. Not dedicated user inputs/outputs, peripherals (e.g. I²C and UART) and RAM locations can be accessed directly according to user's needs.

Details see datasheets of the transceiver modules [7], PIC datasheets [8] and Appendix 1 – RAM and EEPROM maps. In doubt, refer to IQRF support by the manufacturer [6].

Memories

For memory purposes the IQRF OS uses internal memories of the microcontroller only. (TR-5xB also uses external serial EEPROM dedicated to OS, not user accessible.)

Individual parts of memories are:

- Dedicated to the microcontroller
- Dedicated to the OS
- Other areas are available for the user

Memories can be under OS supervision and the user should access them in accordance with this manual and possible requirements resulting from hardware construction of the module and OS implementation.

Illegal modification of dedicated memory locations can cause system crash.

There are several header files (with the .H extension) delivered with IQRF examples and tutorials. They are intended for C compiler to provide easy and seamless linking the OS with the user program. Of course, these text files could serve to user's survey concerning memories – but the user should nowise modify them. (The 16F886.h is based on standard file made by the C compiler manufacturer that is why they contain some IQRF irrelevant information to spare.)

User's own definitions should be placed to extra user header files. Names of user variables must not collide with names predefined in delivered header files.

Refer to Appendix 1 - RAM and EEPROM maps.

Program memory (Flash)

The user can use this as a program memory only. The program remains stored there even after power off. Overwriting is not unlimited, number of erase/write cycles is about 100 000 typically.

User program can be uploaded into the TR module using appropriate IQRF development kits, e.g. CK-USB-04 and IQRF IDE servicing program [9]. Codes in standard .HEX format or encrypted codes in the .IQRF format can be uploaded.

- OS and plug-ins occupy the memory from 0x0000 to 0x1BFF
- Remaining area 0x1C00 – 0x1FFF (1024 machine instructions) is available for user program .

User program should begin from address 0x1C00. It is automatically arranged by the IQRF header files.

Data memory (RAM)

RAM data is fully under supervision of running program and is lost after power off.

Individual RAM parts:

- dedicated to the **microcontroller** and its **peripherals** (PIC special function registers – SFRs). Direct using is mostly restricted, e.g. the application need not use registers INDF, EECON1, EECON2, EEADR, PIR2, PIE1 and PIE2. In doubt, refer to IQRF support by the manufacturer [6].
- dedicated to **OS**:
 - **IQRF communication** (RF and SPI) is packet oriented therefore buffer servicing is supported. There are four basic buffers primarily dedicated to communication and block operation:
 - **bufferRF** (0x110 – 0x14F), 64 B – for RF communication
 - **bufferCOM** (0xA0 – 0xC8), 41 B – for serial communication (especially SPI). Use 35 B (0xA0 – 0xC2) only, the others are reserved for OS and future compatibility.
 - **bufferINFO** (0x20 – 0x42), 35B – for OS and user block operations
 These communication buffers are especially intended for transferred data but can be used according user's need in specific cases as well. There are specialized OS functions for comfortable buffer to buffer data copying.
 - **bufferAUX** (0x1C0 – 0x1DF), 32 B – auxiliary buffer, to store bufferINFO temporarily to make it free for other operations.
 - **buffer networkInfo** (22B) is an area dedicated to network system information.
 - **system variables**. Some of them (toutRF, userStatus etc.) can be directly accessed by the user.
 - **OS work variables** (not documented, the user need not modify them).
- Area (0x190 – 0x1B7) is **available for the user** (40 B). It is located in the RAM bank 3. Selection of bank 3 is automatically arranged by the IQRF header files. Additionally, two **userRegx** registers (0x1F0 and 0x1F1) are available in area shared for all banks. If needed, refer to the PIC datasheets [8] for information about RAM banking.

See Appendix (RAM map).

For block access special OS functions are intended instead of access via FSR and INDF registers which is restricted due to security reasons. Indexes of arrays are not allowed to be variables. (A[1]=0 is allowed, A[i]=0 is restricted due to using FSR by the C compiler). See IQRF OS Reference Guide [1].

Data memory (EEPROM)

EEPROM data remains stored even after power off. Overwriting is not unlimited, number of erase/write cycles is 100 000 min., (typically 1 000 000). EEPROM is especially intended for configuration parameters and data.

Individual EEPROM parts:

- **User data:** 160B from 0x00 to 0x9F (Nodes only). This area is not user available for Coordinators.
- **Application data:** 32 B from 0xA0 to 0xBF (Nodes as well as Coordinators). The user can use this area for his particular needs (especially intended for configuration and similar purposes). It is accessible for reading via the `appINFO()` function in a comfortable way. The factory settings string is: "Hello everybody. IQRF is here! "
- **Dedicated to OS:** (Node as well as Coordinator)
Remaining EEPROM area (0xC0 – 0xFF) is dedicated to OS. It is not accessible by the user.

EEPROM access:

- Values can be specified in application (source) program to be written to EEPROM while the program is uploaded into the microcontroller. EEPROM address range is 0x2100-0x21FF instead of 0x00-0xFF when using `cdata` and similar C statements (e.g. `__EEAPPINFO = 0x21A0`).
- The microcontroller can read/write data from/to EEPROM under user program control while the application is running using general OS functions for accessing EEPROM (`eeWriteByte`, ...). Short addresses (0x00–0xFF) are used in this case. Access via `EEADR` and `EEADTA` registers is restricted due to security. See IQRF OS Reference Guide [1].

The user should avoid exceeding the number of erase/write cycles allowed. Note that also some other OS functions (`bond`, `bondRequest`, ...) write to EEPROM as well.

Identification

Module data

Every IQRF module contains information about itself. This is accessible via the `moduleInfo()` function storing data to the `bufferINFO` in the following format:

address in <code>bufferInfo</code>	7	6	5	4	3	2	1	0
meaning	OS build		PIC type	OS version	Coordinator / Node	serial number		
	Module ID							

Coordinator / Node: reserved for future OS versions (set to 1 in this OS version). Coordinator / Node is SW selectable in IQRF this OS version.

- 0: Node
- 1: Coordinator

OS version:

- upper nibble (4 b): major version
- lower nibble (4 b): minor version

PIC type:

- 3: PIC16F886

OS build: for the manufacturer only. Differences among various builds has no influence to functionality from the user's point of view.

Example (all in hexadecimal):

```

[0] [1] [2] [3] [4] [5] [6] [7]
bufferINFO[0-7] = 1C 10 00 01 30 03 39 11

```

Meaning: Coordinator, Module ID = 0100101C, IQRF OS version 3.00, PIC16F886, build # 0x1139.

Module ID is displayed by the IQRF IDE development environment.

Application data

It is a 32 B block in EEPROM (area 0xA0 – 0xBF) dedicated to the user application. It is possible to read data from it directly to the `bufferINFO` very effectively by a single instruction (`appINFO()`) only. This area is intended for arbitrary information concerning user application but is especially useful for repeatedly employed (often permanent) data such an identification information to be compared after receiving (with the `compareBufferINFO2RF()` function).

Refer to memory maps in Appendix as well.

Control

Operation modes

The TR modules can work in three modes:

- **Programming:** The user program or OS plug-in can be uploaded to the TR (including EEPROM content). This mode is available using the appropriate IQRF development kit and IQRF IDE development environment. See application note AN003 [11].
- **Run:** The TR module executes operation programmed by the user.
- **Debug:** Execution is stopped and data can be downloaded from the microcontroller and displayed by the IQRF IDE. This mode is fully under control of user program and interactive handling in IQRF IDE.

Real time

OS provides an efficient support for real time applications. It has a generator of time intervals running on background and appropriate functions. Basic interval (elementary OS time interval for timing on background – a “tick”) is 10 ms. Specified number of ticks serve for timing of appropriate processes (delays, LED blinking, communication timeout checks, ...) and also enables to create a user timebase. Tick is derived from internal RC oscillator.

- Capture is another efficient timing tool. It is an independent resettable timer (16-bit counter of ticks) freely running on background. It is suitable especially for working with long periods (up to 655s).
- OS provides functions also for waiting on foreground.
- Short time intervals for timing on foreground can be derived also from instruction timing. The PIC16F886 is clocked with internal 8MHz RC oscillator. Thus, instruction cycle is 500ns (1 μ s for some instructions) – see PIC datasheets [8].

Some OS functions (especially `RFRXpacket` and several delays) share the same internal timers that is why these functions should not be used at the same time. Refer to the IQRF OS Reference guide [1], side effects.

Note that time precision of TR modules depends on precision of internal RC oscillator – see PIC datasheets [8]. Microcontrollers are individually calibrated by the manufacturer but despite of this fact the precision and stability are less than for a crystal oscillators. The precision is sufficient for asynchronous communication (UART) with reasonable speed, for clock and calendar functions another suitable method should be used. To increase precision for operations based on ticks, tick duration is calibrated to crystal precision automatically after reset and should be also done by the user (from time to time, in case of temperature or supply voltage change etc.) This is useful especially for IQMESH timing. See the `calibrateTimer()` function in the IQRF OS Reference guide [1].

Watchdog

To increase the reliability, the OS uses hardware watchdog of the microcontroller. It is a continuously running independent timer with a programmable overflow period. It should be used that never overflow during correct operation. It is accomplished via the `clrwdt()` instruction always executed in time, i.e. before the watchdog overflows. (This function is implemented not in OS but it is the PIC machine instruction supported with the C compiler). If an overflow occurs it is regarded as a program execution failure (especially due to an error in algorithm in application program) and the microcontroller responds with reset. If the failure is not a permanent one, it can lead to system recovering. The watchdog can run even in the Sleep mode (see below). Overflow in Sleep results in wake-up and continuing execution but not in the PIC reset.

The watchdog can be enabled/disabled in SW. Overflow period is user selectable (even while the program is running) from 1 ms to 268 ms. Setup registers are WDTCON (WDTPSx and SWDTEN bits) and OPTION (PS0, PS1 and PS2 bits, remaining bits including PSA must be left unchanged by the user) – see PIC datasheets [8]. Default timeout period is about 4s. Watchdog can be disabled by `SWDTEN=0` and reenabled by `SWDTEN=1`.

TR module Sleep

Complete TR module (including the RF circuitry, microcontroller and temperature sensor) can be set in the standby (Sleep) mode. In this case almost no operation is executed but the power consumption is minimized.

Transition to the Sleep mode:

The Sleep mode is initiated in software using the `iqrfSleep()` function in appropriate location in the source program. Then all TR hardware resources controlled by the OS are automatically suspended: activity of the TR module including the RF circuitry, temperature sensor, microcontroller as well as its peripherals (stopping of timers, disconnecting of internal pull-ups, ...).

Before switching to the Sleep mode:

- Power consumption should be minimized even for hardware resources of TR controlled by the user (PIC pins, possible PIC internal peripherals) and possible external peripherals connected. It must be done in user program. See the TR [7]

and PIC [8] datasheets.

- The microcontroller should be configured for subsequent wake-up on pin change (if required):
 - Wake-up on pin change is under user's control, default disabled.
 - To enable, the sequence `GIE = 0; RBIE = 1; iqrfsleep(); RBIF = 0;` is required.

Returning to the operating mode (wake-up):

- after watchdog overflow (if enabled)
- after pin change on some pins (depending on the TR type, typically the C5 pin), when configured as inputs (if enabled)
- after power-off/on

Tip: wake-up types can be identified via the `-TO` and `-PD` status flags – see Reset below.

After the wake-up the microcontroller continues with execution the command following the Sleep function.

The user can use Sleep and wake-up without any restriction due to OS, all related microcontroller possibilities can be employed – see PIC datasheets [8].

Tip: sleep period can be setup via the watchdog timeout period.

Typical sleep power consumption $\sim 2 \mu\text{A}$ can be reached with all peripherals off – see the TR datasheets [7].

RF Sleep

RF circuitry can be set in power saving standby mode while the microcontroller continues running using the `setRFsleep()` function. 0.6 mA typ. is saved. RF response is prolonged for 2 ms typ., 7 ms max. due to wake-up. Wake-up can be caused by `RFRXpacket()`, `RFTXpacket()`, `checkRF(x)` or `getSupplyVoltage()`.

RX chain

After RF transmission is finished RF chains are automatically disabled. In the `Stay in RX` mode the RX chain remains enabled for faster response to following `checkRF`, `RFRXpacket` or `RFTXpacket`.

Other PIC peripherals

There are PIC HW resources (I^2C , UART, ...) not supported with the OS but accessible directly via PIC special function registers. Refer to datasheet of the microcontroller [8].

Reset

The following reset types available:

- **Power-on reset:** Utilizes HW filter to eliminate improper power-up rising and spikes to some extent. A lot of applications need no external reset circuitry.
- **Watchdog reset:** After WDT time-out.
- **Brown-out reset:** If power supply falls below given level for given time the reset is invoked. This option is disabled but can be enabled by the manufacturer on request. Then it is possible to have it enabled during operation and disabled in Sleep.

Reset can also be invoked by SW via the `reset()` function. It is the watchdog reset type.

To identify reset type four status flags are available in the userReg0 just after boot:

bit	7	6	5	4	3	2	1	0
Status flag				-TO	-PD		-POR	-BOR

-TO Watchdog time-out flag

-TO = 0 after `reset` execution, WDT overflow or `reset()` function.

-TO = 1 after power-up, `clrwdt` or `iqrfsleep`

-PD Power-down flag

-PD = 0 after `iqrfsleep`

-PD = 1 after power-up or `clrwdt`

-POR Power-on reset flag

-POR = 0 after power-on reset (must be set in software then)

-POR = 1 no power-on reset occurred

-BOR Brown-out reset flag

-BOR = 0 after Brown-out reset (must be set in software then)

-BOR = 1 no Brown-out reset occurred

Refer to the PIC datasheet [8], (`STATUS` and `PCON` registers) for details.

Content of RAM registers after resets is strictly defined (set / cleared / not affected / unknown). It partly depends on reset type. Refer to datasheet of the microcontroller [8]. Additionally, OS clears the user memory area and keeps the `userStatus` register unchanged after `reset()`.

Tip: `userStatus` can be used to help to debug unexpected resets in user programs.

Temperature measurement

Temperature is measured by the on-board sensor using internal A/D converter of the microcontroller (TR-52B only). See `E08-TEMPERATURE` example [10] and IQRF OS Reference guide [1].

Battery check

See `getsupplyVoltage()` in IQRF OS Reference guide [1].

LED indication

Two on-board LEDs (red and green) can be served by the set of specialized functions running on OS background.

Debug

The IQRF platform provides user with an efficient debugging tool. To enjoy its powerful capabilities, the following configuration should be used: The transceiver module plugged e.g. into the CK-USB-04 development kit connected to PC via USB with the IQRF IDE development environment [9].

Debug is directly supported by the OS with the `debug()` function. This can be included in user program wherever you need to stop program executing and evaluate variables, EEPROM content or RAM registers. After uploading user program into the transceiver module the application is running until the `debug()` function is encountered. Then the program stops, the module is switched to the debug mode and data is downloaded and displayed on the screen.

The module stays in debug mode till the user wishes. Then the application program can continue execution until another `debug()` function is encountered and so on. To identify individual debug breakpoints the `W` register can be used. See IQRF IDE Help and `E06-RAM` example [10] for details.

SPI

Standard serial 4-wire bus running in OS background. See separate User's guide, Implementation in IQRF TR modules [5].

RF

RF overview

OS functions allow powerful and user-friendly control of RF communication. From the user's point of view it means working primarily with memory and buffers (R/W operations with RF communication buffer). IQRF OS automatically provides all needed services including full protocol implementation:

- at transmission level: HW setup, coding for transmission, timeouts, ...
- at packet level: preamble, consistency checking, coding, ...
- at network level: routing, including information about the network and device, filtering, discovery, ...

Supported modes:

- **Peer-to-peer:** Two or more peer-to-peer devices, without a network Coordinator. Packets are available for all devices in range and completely managed by the user program. Number of devices is unlimited. Keep `PIN=0` (see below) in this mode. This is the default mode.
- **IQMESH:** Topology with one Coordinator mastering the network and up to 65 000 end devices (Nodes) and up to 239 devices in routing structure (backbone) with full network support. This mode is defined by setting the most significant bit (`_NTWF`) of the PIN register to 1. Nodes must be assigned (bonded) to the Coordinator's network. Peer-to-peer ("non-networking") packets are also allowed in IQMESH.

Memory locations and registers related either to Peer-to-peer or IQMESH:

<code>bufferRF[64]</code>	Buffer for RF routines (data to be sent by <code>RFTXpacket</code> or received by <code>RFRXpacket</code>), 64B
<code>PIN</code>	Packet information. See below.
<code>RX</code>	Packet address (specify before transmitting)
<code>TX</code>	Original packet sender (set by OS during receiving)
<code>DLEN</code>	Packet length (number of relevant bytes in <code>bufferRF</code>), 0-64 (specify before transmitting, set by OS after receiving)
<code>toutRF</code>	Timeout for packet receiving (1-255) in number of 10 ms ticks or for LP and XLP modes in cycles (RFIC On-Off periods). Default value is 50 (500 ms in STD mode).

IQMESH network and its individual devices can be configured very flexibly. IQMESH as well as peer-to-peer packets can be sent and received depending on setup of respective devices. Nodes can be assigned to groups. Individual and broadcast packets (for all network members) are supported and user addressing is allowed. IQMESH protocol has been defined as a light and portable to inexpensive microcontrollers with limited resources. One or two byte addressing is chosen.

Every IQRF device can simultaneously work in two independent networks. This OS version supports two networks for every device, working as a Coordinator in one network and as a Node in second network. It allows chaining networks up to unlimited number of devices and easy data sharing. Non-networking packets and packets coming from the other network can be filtered. Background routing is fully supported. Each Node can provide background routing service for network packets or can be programed as a dedicated router. Both Coordinator and Node can be realized by a more complex device, a Gateway, providing an interface between IQMESH and other standards.

Although IQMESH is very flexible and supports high variability and dynamic changes in configuration (including changes in topology), it is primarily intended for more or less static systems. Devices are included in/excluded from the network by the bonding/unbonding procedure which should be considered to be an installation process by its nature. The Coordinator is not intended to be switched dynamically from device to device in a network. The Coordinator should manage RF communication in the whole network. Nodes are allowed to communicate anytime but it can be recommended just in special cases. In typical applications the Coordinator always initiates any communication. All IQMESH communication is coded. The coding differs from network to network being readable in given network only. In addition to "user" packets, IQMESH uses also system packets with auxiliary information (e.g. for bonding, routing etc.). Such system packets are completely transparent from the user's point of view.

Basic network information about current setup of given device (network identification, device number, current network, topology, ...) provides the `getNetworkParams()` function.

RF networking

IQMESH packet transmission is supported by a lot of additional sophisticated features. The communication is possible even between nodes out of RF range each other – using “hops” via other nodes in range (routing). In addition to the normal operation, every IQMESH device (TR module, gateway, ...) can work also as a router on background. IQMESH can additionally contain specialized plug-and-play routers.

Packets for Peer-to-peer communication consists of three block - PAH (packet header), DATA and CRC, while IQMESH packets consists of four blocks - PAH, NTWINFO (networking information), DATA and CRC. Every block has its own consistency check mechanism (CRCs) to achieve high reliability.

PIN	DLEN	CRCH	Networking info	CRCN	User data	CRCD	CRCS
PAH			NTWINFO	DATA		CRC	

PAH

Packet header, 3 bytes long block, carries basic information about a packet, such as data length and flags (whether the packet is intended for peer-to-peer or IQMESH, indication of system communication, routing, direct peripheral addressing, encryption and acknowledgment request).

PIN

bit	7	6	5	4	3	2	1	0
	<code>_NTWF</code>	<code>_ACKF</code>	<code>_ROUTEF</code>	<code>_CRYPTF</code>	<code>_MPRWF</code>	<code>_SYSPF</code>	<code>_TIMEF</code>	<code>_AUXF</code>

`_NTWF`:

- `NTWF = 0` Peer-to-peer mode
- `NTWF = 1` IQMESH mode

`_ACKF`:

Acknowledge request (specify request to the packet before TX, accomplish request after RX). Handling with this flag and all acknowledge processing is fully up to the user (OS just transfers this flag without any consequences).

`_ROUTEF` (for IQMESH mode only):

- `ROUTEF = 0` Routing not required for outgoing packets.
- `ROUTEF = 1` Routing required for outgoing packets, routing registers `RTDT0-3` must be defined.

`_CRYPTF`:

Crypting requested. Reserved for future use.

`_MPRWF` (intended only for special applications supporting direct access to peripherals and services):

- `MPRWF = 0` Module peripheral read/write not active
- `MPRWF = 1` Module peripheral read/write active. `MPRW0-2` is added to `NTWINFO` by OS.

`_SYSPF`:

Dedicated to OS, not intended for users.

`_TIMEF`:

Dedicated to OS, not intended for users.

`_AUXF`:

Reserved for future use.

NTWINFO (applies for IQMESH mode only)

Networking information block with variable length based on `PIN` flags. Just five bytes (`RX` to `PID`) are mandatory (present in every IQMESH packet), the others depend on actual situation. For example, Star topology does not need routing information. Setting `ROUTEF = 0` will make a packet without routing, while after setting `ROUTEF = 1` six bytes describing the routing are expected to be added to the `NTWINFO`. This mechanism provides a way to fit various application needs. `NTWINFO` registers are set by the sender and are passed to all recipients via the packet. Thus, the recipient know which hop is actually in question and how long it is to wait before possible forwarding.

RX	TX	...	PID	RT0TX	RTDEF	RTDT0-3	MPRW0-2
----	----	-----	-----	-------	-------	---------	---------

`RX` Address of the device the packet is intended to in current network:

- 0 Coordinator
- 1 - 239 Nodes
- 240 - 253 Reserved
- 254 Universal address – see `bondNewNode()`
- 255 Broadcast

This must be specified by the user before sending an IQMESH packet.

TX	Address of transmitting sender. It is automatically set by OS by <code>RFTXpacket()</code> .
PID	Packet identification (can be set by the user, e.g. not to respond twice to the same packet). See example E11-IQMESH-N [10].
RTOTX	For OS only.
RTDEF	Routing algorithm.
RTDT0-3	Routing data. See below.
MPRW0-2	Reserved for Direct peripheral access.

User data

Data from/to the `bufferRF`. The length can vary between 0 and 64 B.

RF transmitting

It is possible to combine sending peer-to-peer and IQMESH packets (depending on the NTWF flag).

- Peer-to-peer: Prepare data to the `bufferRF`, specify data length (`DLEN = ...`) and simply send the packet via the `RFTXpacket()`. All receivers obtain the data and `DLEN` only.
- IQMESH: To send IQMESH packets, an appropriate setup (Coordinator/Node selection etc.) should be done and the Node should be bonded to a network. Sending itself is similar to Peer-to-peer but the receiver address (and possible routing information) must be specified. Other networking information is added to the packet by OS automatically.

If bidirectional communication, `PIN` and `DLEN` should be updated before every transmitting followed after any reception.

Packets can be sent in several modes in dependency on receiver mode.

See the IQRF OS Reference guide [1] (`RFTXpacket()`) and examples E01-TX, E03-TR and E09-LINK [10].

RF receiving

The `RFRXpacket()` function attempts to receive a packet and returns control to application after successful reception or after the timeout. Timeout during packet receiving terminates the reception except of the Wait packet end option is enabled.. The user has full control on timing as the timeout can be set in ticks (~10ms in STD RX mode or in cycles ~40 ms in LP RX or ~600 ms in XLP RX) prior to the `RFRXpacket()` function call (`toutRF = ...`).

Result (the `RFRXpacket()` return value) depends on the conditions (filtering, current network, RX mode, packet type, adresse etc.).

To achieve desired noise immunity, programmable signal strength filtering is applied in LP, XLP and SSF RX modes (see below). Incoming signal with lower level than one of four predefined values is ignored. Relative RF range is shortened due to this filtration.

After successful reception respective values are valid: received data in `bufferRF`, data length (`DLEN`) and possibly all other networking information.

To achive ultra low power consumption, the following RX modes are available:

- STD: standard
- LP (low power): receiving combined with standby mode. Incoming packets should be detected by `RFRXpacket()` (utilizing signal strenght filtering) but not by `checkRF(x)`.
- XLP (extra low power): receiving combined with deep standby mode. Incoming packets should be detected by `RFRXpacket()` (utilizing signal strenght filtering) but not by `checkRF(x)`.
- RFIM (RF Immunity Mode): `RFRXpacket()` is prematurely terminated if RF signal falls below predefined level specified in the `sefRFmode(x)` function, bits `FF`. This should be used with `checkRF()` only: `if checkRF() ...`

See the IQRF OS Reference guide [1], `RFRXpacket()` and examples E02-RX, E03-TR and E09-LINK [10].

Filtering

In case of chaining networks it can be selected whether packets should be received from both networks (including peer-to-peer packets) or from the current network only. If filtering is off current network is automatically switched to the network the packet was received from.

Addressing

There are 3 types of addresses – see below (Routing, Addressing overview):

- Logical address: created by bonding.
- User address: created by `setUserAddress(x)`.
- Virtual routing number, VRN: created by Discovery. For OS only. The user need not take care about VRNs at all.

Routing

Routing allows sending packets to addressees out of the sender's range using "hops" via devices which are in range each other. This IQRF OS supports up to 239 routing devices for a packet. Routing is separated from addressing and is transparent from the user's point of view. There are several routing algorithms specified in the `RTDEF` register according to network topology. Packet is routed via devices in specified order (routing vector) in defined time slots with specified period each. Retransmitting passes in reverse order. OS ensures that the packet is ignored by all devices except of the addressee and the devices specified in the routing vector.

For effective IQMESH the topology (placement of devices with respect to the range) should be designed in a redundant way - every device should have sufficient number of devices in range. Routing algorithm should be specified with respect to reliability and speed requirements. Due to time slots the efficiency should considerably depend on the order in the routing vector as well. The Addressee does not route the packet except of a broadcast one.

Thus, routing allows higher range, lower RF output power, more ways to deliver packets, higher noise immunity, resistance against failures and dropouts (self-healing) and flexibility with respect to dynamic changes in range among individual devices (moving of persons, obstacles or devices themselves) which results in better throughput and reliability.

Routing can be enabled or disabled for individual nodes. Routed packets can be received whenever the `RFRXpacket()` is active in routing device but they can be retransmitted in respective time slots only.

Discovery

Nodes can be placed according to their addresses (with respect to fixed routing vector 1, 2, 3, ...) or in a random order. But the random order requires Discovery when internal routing backbone is created and routing paths are found automatically.

Discovery assorts Nodes to zones (groups of Nodes which can be reached by the same number of hops from the Coordinator). Number of zones can be limited by the user.

During Discovery the `answeSystemPacket()` function must run in a loop in every Node to be discovered. It is recommended to run Discovery with stronger filter then it is planned for common communication (lower RF power on the Coordinator side or stronger RSSI filter on the Node side – see example `E11-IQMESH-N` [10]). Nodes answer with the same output power (possible restoration is up to the user). Number of discovered nodes can be less than number of bonded nodes. Discovery results also depends on the `setRoutingOff()` function in Nodes.

After changes influencing the range (changes in topology, addressing, device placement, obstacles, permanent failure of a router etc.) the Discovery should be reinvoked.

Routing is possible under all following conditions:

- The routing device is bonded to respective network
- The packet was sent by the original sender with routing requirement (`ROUTEF = 1`)
- The `RFRXpacket()` function is active in the routing device when the packet to be routed is sent.
- *The `ROUTEF` flag relates to outgoing packets and has no influence to routing incoming packets at all.*

Dedicated router for STD packets doing nothing but background routing can be realized very simply by a neverending loop:

```
setNodeMode();
while (1)
{
    RFRXpacket();
    clrwdt();
}
```

It assumed this device has already been bonded. Due to power consumption it is recommended to supply such a router from mains adapter. Battery operated routers should use the LP or XLP receive modes.

Every application has usually very different requirements. For example, a typical Smart House application can be realized with 4 hops and there is a need for fast response, while collecting data from power meters usually needs a network supporting much more hops but the latency is allowed. Thus, IQMESH specification supports various routing algorithms.

IQMESH allows up to 65 000 devices in single network but only 239 of them are allowed to route.

All algorithms works with the following parameters:

- **RTDT0:** number of hops per packet (0 – 239). 0 means direct delivery (without routing), e.g. 2 means 3 packets sent. It should be set according to topology (e.g. number of bonded Nodes in case of chain MESH). *RTDT0* is decremented in each hop.
- **RTDT1:** time slot duration (in ticks). It should be longer than the transmit time for given packet. It depends on number of user data to be sent, *PIN*, *DLEN*, RF mode and RF speed. It can be approximately evaluated (in ticks) for 19.2 kb/s:
 - **STD:** (1 or 2) + 1 for every 24 B of user data
 - **LP:** (5 or 6) + 1 for every 24 B of user data
 - **XLP:** 120
- **RTDT2:** DID (Discovered ID) – identification of Discovery. Not set by the user.
- **RTDT3:** Upper byte of user address if user addressing is used.

If number of hops = number of bonded nodes the routing is very robust (flooding). But even flooding is no assurance that the packet is successfully routed (overdue if unsuitable order of Nodes).

Routed packet is delivered in frame = time slot length x number of hops and **must not be answered until the frame is elapsed** otherwise a collision with routing devices occurs. Time starts from the packet sent by the Coordinator (the first slot is dedicated to the Coordinator). See example E11-IQMESH-N [10]).

Routing algorithms

• SFM (Static Full MESH)

Up to 240 devices in a network is allowed. Routing vector is fixed (1, 2, ..., 239), logical addresses are used for addressing (*RX* = logical address). Broadcast address is 0xFF. Bonding can be done before placement, addresses must be known and devices must be placed with respect to topology (addresses should increase with the distance from the Coordinator). Discovery is no use.

Example: Selecting *RTDT0*=4 (4+1 hops) and *RTDT1*=5 (50 ms time slot) is analogic to the only routing algorithm in OS v2.xx.

• DFM (Discovered Full MESH)

Up to 240 devices in a network is allowed. Random placement is allowed and addresses need not be known for routing purpose but Discovery has to be performed after placement and bonding. Routing uses renumbered addresses (VRN, Virtual Routing Numbers) as a result of the Discovery process which creates a routing backbone with up to 240 devices divided to zones (based on minimal number of hops to individual Nodes). VRNs increase with the distance from the Coordinator (virtual routing backbone), are intended for OS only, the user need not take care about it. After a change in topology Discovery should be repeated. DFM is analogic to SFM but VRNs are used for routing instead of logical addresses. User addressing is completely the same (*RX* = logical address). Broadcast address is 0xFF.

1 – 9: logical addresses, 1 – 9: VRNs, Z1 – Z4: zones.

• **DOM (Discovered Optimized MESH):** DOM is a special case of DFM. It is quite the same but number of hops is optimized (reduced) by the `optimizeHops()` function. It sets the *RTDT0* (number of hops) according to Discovery results to VRN of addressed Node to speed up the transmission at the cost of reduced redundancy.

• DFM2B (Discovered Full MESH, 2 B)

The same as DFM but up to 65 000 devices and virtual routing backbone with up to 239 Nodes in a network is allowed. 2 B user addressing must be used based on `setUserAddress(x)`. Addressing: *RTDT3* = high byte, *RX* = low byte. Broadcast address is 0xFFFF. Groups can be created by assigning the same addresses to more Nodes. `optimizeHops()` is not intended for DFM2B. See IQRF OS Reference guide [1], `bondNewNode()` and `setUserAddress()` for details.

• **Tree:** Just one router in every zone is used. It is the fastest way to return packets back to the Coordinator but without a redundancy at all. It works for packets from Nodes to the Coordinator only. *Not fully implemented and tested yet.*

Tip: Routing algorithms can be mixed each other. Thus, the user can use faster algorithm first and then more redundant one(s) for not responding Nodes only.

Addressing overview

Routing algorithm	RTDEF	Address range	Addressing by	Addressing	Broadcast address
Not implemented	0x00	–	–	–	–
SFM	0x01	1 to 239	logical address	RX = ...	0xFF
DFM	0x02	1 to 239	logical address	RX = ...	0xFF
DFM2B	0x42	1 to 65 000	user address	RTDT3 = high byte RX = low byte	0xFFFF
Tree	0x08	1 to 239	logical address	RX = ...	0xFF

Bonding

Devices are bonded to an IQMESH network when they are assigned to given Coordinator. Bonding is a mutual relationship between Coordinator and Node. Coordinator assigns a number (1 to 239) to the Node which can serve as device address. This short (1 B) address is used within the network. Individual network is identified via the unique four byte Module ID of the Coordinator - see Identification. This long ID is used outside the network.

Bonding is based on Node request (`bondRequest()`) confirmed by the Coordinator (`bondNewNode()`) via exchanging RF system packets. RF power is not limited by OS during bonding. To avoid possible influence on other modules, bonding can be performed on minimal distance with RF power lowered by the user.

The following bonding information is written in system EEPROMs (but they are not intended for direct user access):

- Coordinator:
 - Bit array. Individual flags = 1 if respective Node is bonded on Coordinator side
- Node:
 - Node number: short (1 B) device address
 - Network identification (4 B)
 - Flag if the Node is bonded on Node side

Address assigned by bonding can be specified by the user. If omitted, default is number of bonded nodes + 1. Thus, `bondNewNode(0)` is suitable for the initial bonding without discontinuities due to possible previous unbondings only.

The user can check results and make arbitrary changes in bonding at any time. There is a set of OS functions dedicated to bonding and related operations (access results, unbonding, rebonding etc). But once the Node is bonded and respective records are written to EEPROMs on both sides, Coordinator as well as Node starts keeping its own bonding information independently and no subsequent changes in bonding are carried over to opposite side via RF automatically arranged by OS.

In short, only `bondRequest` and `bondNewNode` exchange RF system packets between Coordinator and Node. All subsequent changes in bonding by either Coordinator or Node are written to EEPROM just on one side. For example, `removeBondedNode()`, `rebondNode()` and `clearAllBonds()` operate with the Coordinator bit array only and `removeBond` operates with the Node flag only. If synchronization between Coordinator and Node after changes is needed it must be done by the application program. Static systems that suit IQRF best have moderate requirements for changes in bonding.

If you need a help or more information please visit IQRF support pages [6] and Submit a Ticket with your request. A lot of information is also available in the IQRF OS User's guide [1] and on the IQRF home page [3].

Document revision

- 110621 Do not switch MCU clock from 8 MHz to another one (page 7).
- 110124 Importance of time frames highlighted on page 17. Configuration words and related information updated.
- 110112 Information added and precised
- 101223 Preliminary release, OS v3.00

If you need a help or more information please visit IQRF support pages [6] and Submit a Ticket with your request. A lot of information is also available on the IQRF web site [3].
